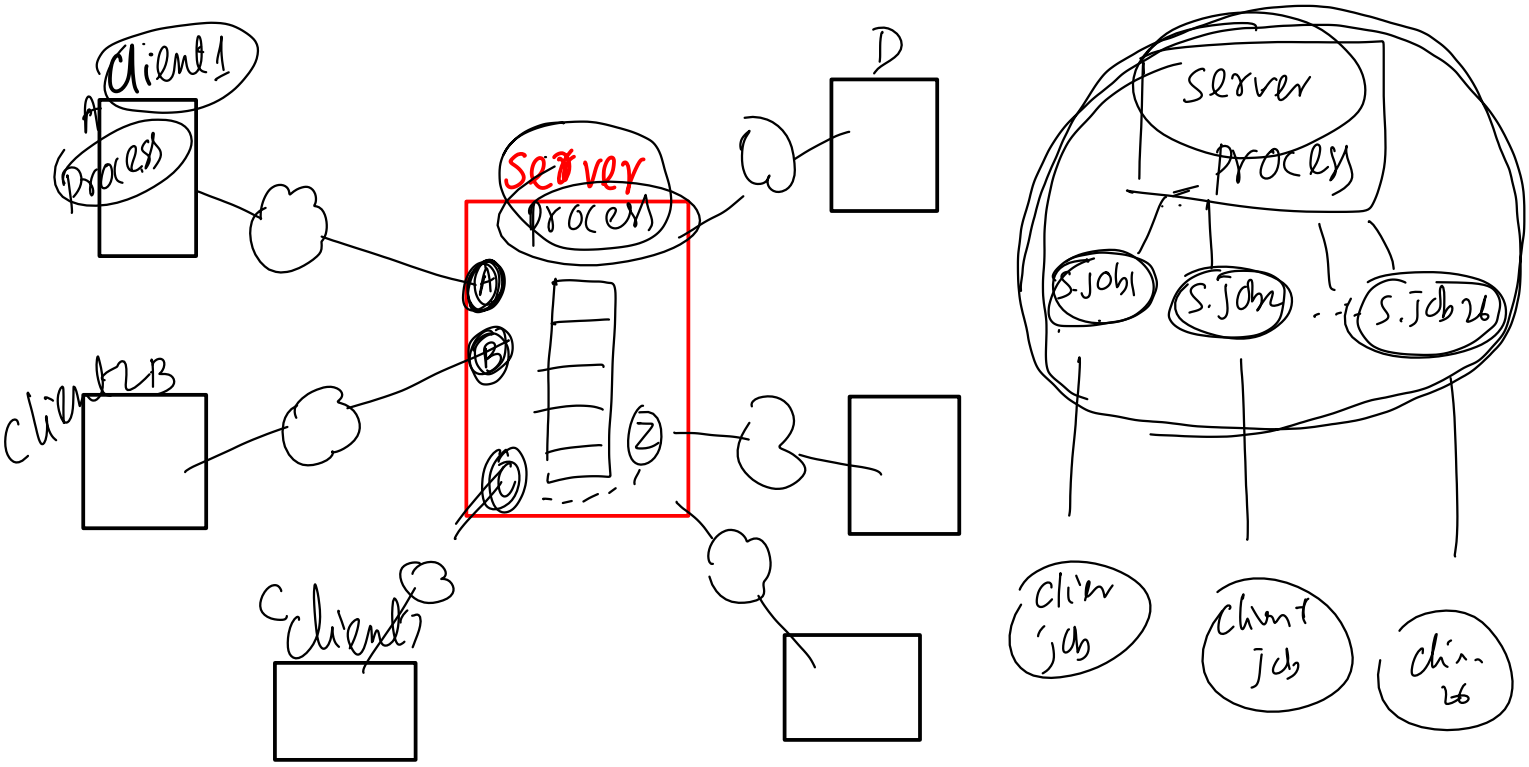
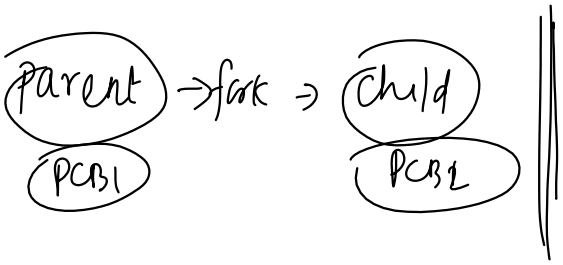
What is thread, how is it different from process?

Write a program to demonstrate threads executing concurrently.
Write a program to demonstrate processes executing cocurrently.





---

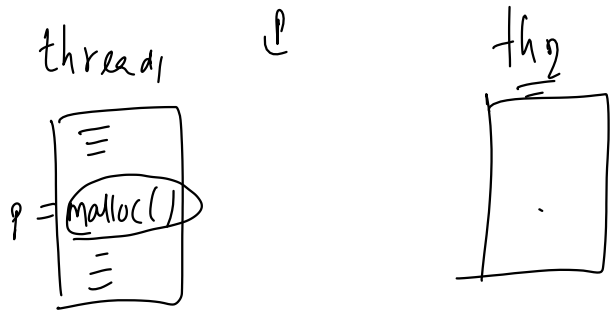
child job inherits the properties from parent.

But Addr Space made separate

threads are designed to share the addr space of the creator. that means all the threads of a process belong to common Addr Space (Page table)

→ Every thread is an ~~independent~~ unique task.

→ If the thread sharing the page of process, ~~it~~ does it have any separate page?



→ fork is the most common system call to create a new job. process.

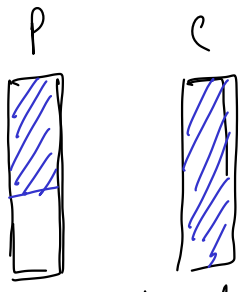
→ fork returns
- 0 to child
- Non-zero (Child Id) to parent.

→ As ~~at~~ addr copy diff, Any ~~d~~ common data modified exclusively in par/child, doesn't reflect ~~in~~ other.

→ It's obvious that child turns orphan or Zombie

→ How to avoid child becoming orphan?

→ wait / waitpid



the wait() in parent, Blocks the parent, until the child gets terminated

→ How to avoid child becoming zombie?

→ wait / waitpid
